Sociological barriers

Energy storage technology advancements have transformed electric vehicles (EVs) from pure curiosity into reasonably priced and effective automobiles. Nevertheless, societal and technological obstacles continue to exist, limiting EVs' potential to have an even greater market impact.

There are some problems that science and technology could solve, and these electric cars can be proven to be highly effective systems." But there are still unanswered questions. We refer to it as range anxiety, for example.

The current generation of EV batteries is limited to a 300-mile driving range on a single charge. Drivers often feel anxious when pulling into charging stations because you can't pull into one the same way you can at a gas station, especially on long trips.

87% of cars on the road could be replaced by electric vehicles that meet or surpass daily needs without daytime recharging. A recent study suggests that range anxiety may be more psychological than technical.

Transforming the grid

In terms of greenhouse gas emissions, the energy sector is in the lead, even though the transportation sector may come in second. Researchers believe that in order to support global

sustainability, EVs and a green energy grid go hand in hand, with the essential advancement in energy storage serving as their common denominator.
